

4.6.4 VOLCANIC HAZARDS

Volcanic hazards include the effects of lava flows, fissures, uplift, subsidence, volcanic earthquakes, and ash flows or airborne ash deposits (Hackett and Smith 1994). Most of the basalt volcanic activity occurred from 4 million to 2,100 years ago in the INEEL area. The most recent and closest volcanic eruption occurred at the Craters of the Moon National Monument 26.8 miles southwest of INTEC's main stack (Kuntz et al. 1992). Based on probability analysis of the volcanic history in and near the south central INEEL area, the Volcanism Working Group (VWG 1990) estimated that the conditional probability that basaltic volcanism would affect a south-central INEEL location is less than once per 100,000 years or longer. The probability is associated primarily with the Axial Volcanic Zone and the Arco Volcanic Rift Zones. INTEC is located in a lesser lava flow hazard area of INEEL, more than 5 miles from the Axial Volcanic Zone and any volcanic vent younger than 400,000 years. The probability that basaltic

volcanism would affect a south-central INEEL location is less than 2.5×10^{-5} (once per 40,000 years or longer. Because of the low probability of volcanic activity during the project duration, volcanism is not discussed further in this section.

4.7 Air Resources

This section describes the air resources of INEEL and the surrounding area. The discussion includes the climatology and meteorology of the region, a summary of applicable regulations, descriptions of radiological and nonradiological air contaminant emissions, and a characterization of existing levels of air pollutants. Emphasis is placed on changes in air resource conditions since the characterization performed to support the SNF & INEL EIS, Volume 2, Part A, Section 4.7 (DOE 1995), from which this EIS is tiered. Additional detail and background information on the material

is presented in Appendix C.2, Air Resources.

4.7.1 CLIMATE AND METEOROLOGY

The Eastern Snake River Plain climate exhibits low relative humidity, wide daily temperature swings, and large variations in annual precipitation. Average seasonal temperatures measured onsite range from 18.8°F in winter to 64.8°F in summer, with an annual average temperature of about 42°F (DOE 1995). Temperature extremes range from a summertime maximum of 103°F to a wintertime minimum of -49°F. Annual precipitation is light, averaging 8.7 inches, with monthly extremes of 0 to 5 inches. The maximum 24-hour precipitation is 1.8 inches. The greatest short-term precipitation rates are primarily attributable to thunderstorms, which occur approximately 2 or 3 days per month during the summer. Average annual snowfall at INEEL is 27.6 inches, with extremes of 59.7 inches and 6.8 inches.

Affected Environment

Most onsite locations experience the predominant southwest/northeast wind flow of the Eastern Snake River Plain, although terrain features near some locations cause variations from this flow regime. The wind rose diagrams in Figure 4-8 show annual wind flow. These diagrams show the frequency of wind direction (i.e., the direction from which the wind blows) and speed at three of the meteorological monitoring sites on INEEL for the period 1988 to 1992. Multi-year wind roses exhibit little variability and are representative of typical patterns. INEEL wind rose diagrams reflect the predominance of southwesterly winds that result during storm passage and from daily solar heating. Winds from this direction are frequently unstable or neutral, promote effective dispersion, and extend to a considerable depth through the atmosphere. At night, cool, stable air frequently drains down the valley in a shallow layer from the northeast toward the southwest. Under these conditions, dispersion is limited until solar heating the following day mixes the plume through the mixed depth or the height above the ground to which the plume can freely diffuse. Winds above such stable layers exhibit less variability and provide the transport environment for materials released from INEEL sources.

The highest hourly average near-ground wind speed measured onsite is 51 miles per hour from the west-southwest, with a maximum instantaneous gust of 78 miles per hour (Clawson et al. 1989). Other than thunderstorms, severe weather is uncommon. Five funnel clouds (tornadoes not touching the ground) and no tornadoes were reported onsite between 1950 and 1997. Visibility in the region is good because of the low moisture content of the air and minimal sources of visibility-reducing pollutants. At

Craters of the Moon National Monument, which is approximately 27 miles west-southwest of INTEC, the annual average visual range is 144 miles (visual range at the time the SNF & INEL EIS analyses were performed was 97 miles) (Notar 1998).

4.7.2 STANDARDS AND REGULATIONS

Air quality regulations have been established to protect the public from potential harmful effects of air pollution. These regulations (a) designate acceptable levels of pollution in ambient air, (b) establish limits on radiation doses to members of the public, (c) establish limits on air pollutant emissions and resulting deterioration of air quality due to vehicular and other sources of human origin, (d) require air permits to regulate (control) emissions from stationary (nonvehicular) sources of air pollution, and (e) designate prohibitory rules, such as rules that prohibit open burning.

The Clean Air Act (and amendments) provides the framework to protect the nation's air resources and public health and welfare. In Idaho, the U.S. Environmental Protection Agency and the State of Idaho Department of Health and Welfare, Division of Environmental Quality, are jointly responsible for establishing and implementing programs that meet the requirements of the Clean Air Act. INEEL activities are subject to air quality regulations and standards established under the Clean Air Act and by the State of Idaho (IDHW 1997) and to internal policies and requirements of DOE.

INEEL occupies portions of 3 counties (Butte, Jefferson, and Bingham) in east-central Idaho

that are in attainment or are unclassified for all National Ambient Air Quality Standards. Parts of Bannock County (approximately 30 miles southeast of the INEEL boundary) and Power County (approximately 35 miles south of the INEEL boundary) are designated nonattainment areas for a single criteria pollutant, particulate matter (PM-10). Air quality standards and programs applicable to INEEL operations are summarized in Appendix C.2.

4.7.3 RADIOLOGICAL AIR QUALITY

The population of the Eastern Snake River Plain is exposed to environmental radiation of both natural and human origin. This section summarizes the sources and amounts of radiation exposure in this geographical

region, including sources of airborne radionuclide emissions from INEEL.

4.7.3.1 Sources of Radioactivity

The major source of radiation exposure in the Eastern Snake River Plain is natural background radiation. Sources of radioactivity related to INEEL operations contribute a small amount of additional exposure.

Background radiation includes sources such as cosmic rays; radioactivity naturally present in soil, rocks, and the human body; and airborne radionuclides of natural origin (such as radon). Radioactivity still remaining in the environment as a result of worldwide atmospheric testing of nuclear weapons also contributes to the background radiation level, although in very small amounts. The natural background dose for residents of the Eastern Snake River Plain is estimated at about 360 millirem per year, with more than half (about 200 millirem per year) caused by the inhalation of radioactive particles formed by the decay of radon (DOE 1997a).

INEEL operations can release radioactivity to air either directly (such as through stacks or vents) or indirectly (such as by resuspension of radioactivity from contaminated soils). Emissions from INEEL facilities include radioisotopes of the noble gases (argon, krypton, and xenon) and iodine; particulate fission products, such as ruthenium, strontium, and cesium; radionuclides formed by neutron activation, such as tritium (hydrogen-3), carbon-14, and cobalt-60; and heavy elements, such as uranium, thorium, and plutonium, and their decay products. Table 4-9 provides a summary of the principal types of airborne radioactivity emitted during 1995 and 1996 from INEEL facilities. Releases during this period exclude calciner operations but are more conservative in that the maximally exposed individual (MEI) dose was higher.

Table 4-9. Summary of airborne radionuclide emissions (in curies) for 1995 and 1996 from facility areas at INEEL.^{a,b}

a. Source: DOE (1996, 1997b). Used 1995 and 1996 sources based on most recent years that calciner did not operate because calciner is considered an impact.

b. Emissions are representative of years, in which calcining does not occur.

c. Mixed fission and activation products that are primarily particulate in nature (e.g., cobalt-60, strontium-90, and cesium-137).

d. U/Th/TRU = Radioisotopes of heavy elements such as uranium, thorium, plutonium, americium, and neptunium.

e. – = Negligibly small or zero.

f. RWMC = Radioactive Waste Management Complex.

4.7.3.2 Existing Radiological Conditions

Monitoring and assessment activities are conducted to characterize existing radiological conditions at INEEL and the surrounding environment. Results of these activities show that exposures resulting from airborne radionuclide emissions are well within applicable standards and are a small fraction of the dose from background sources. These results are discussed in the following sections for both onsite and off-site environments.

It is important to note that characterizations of existing conditions described in this section do not take into account increases in radionuclide emissions and radiation doses that are projected to occur between the present and the time that the alternatives proposed in this EIS would be implemented. These “reasonably foreseeable increases” are assessed in combination with existing conditions and impacts associated with the proposed alternatives in Section 5.4, Cumulative Impacts.

Radiation Levels on and Around INEEL

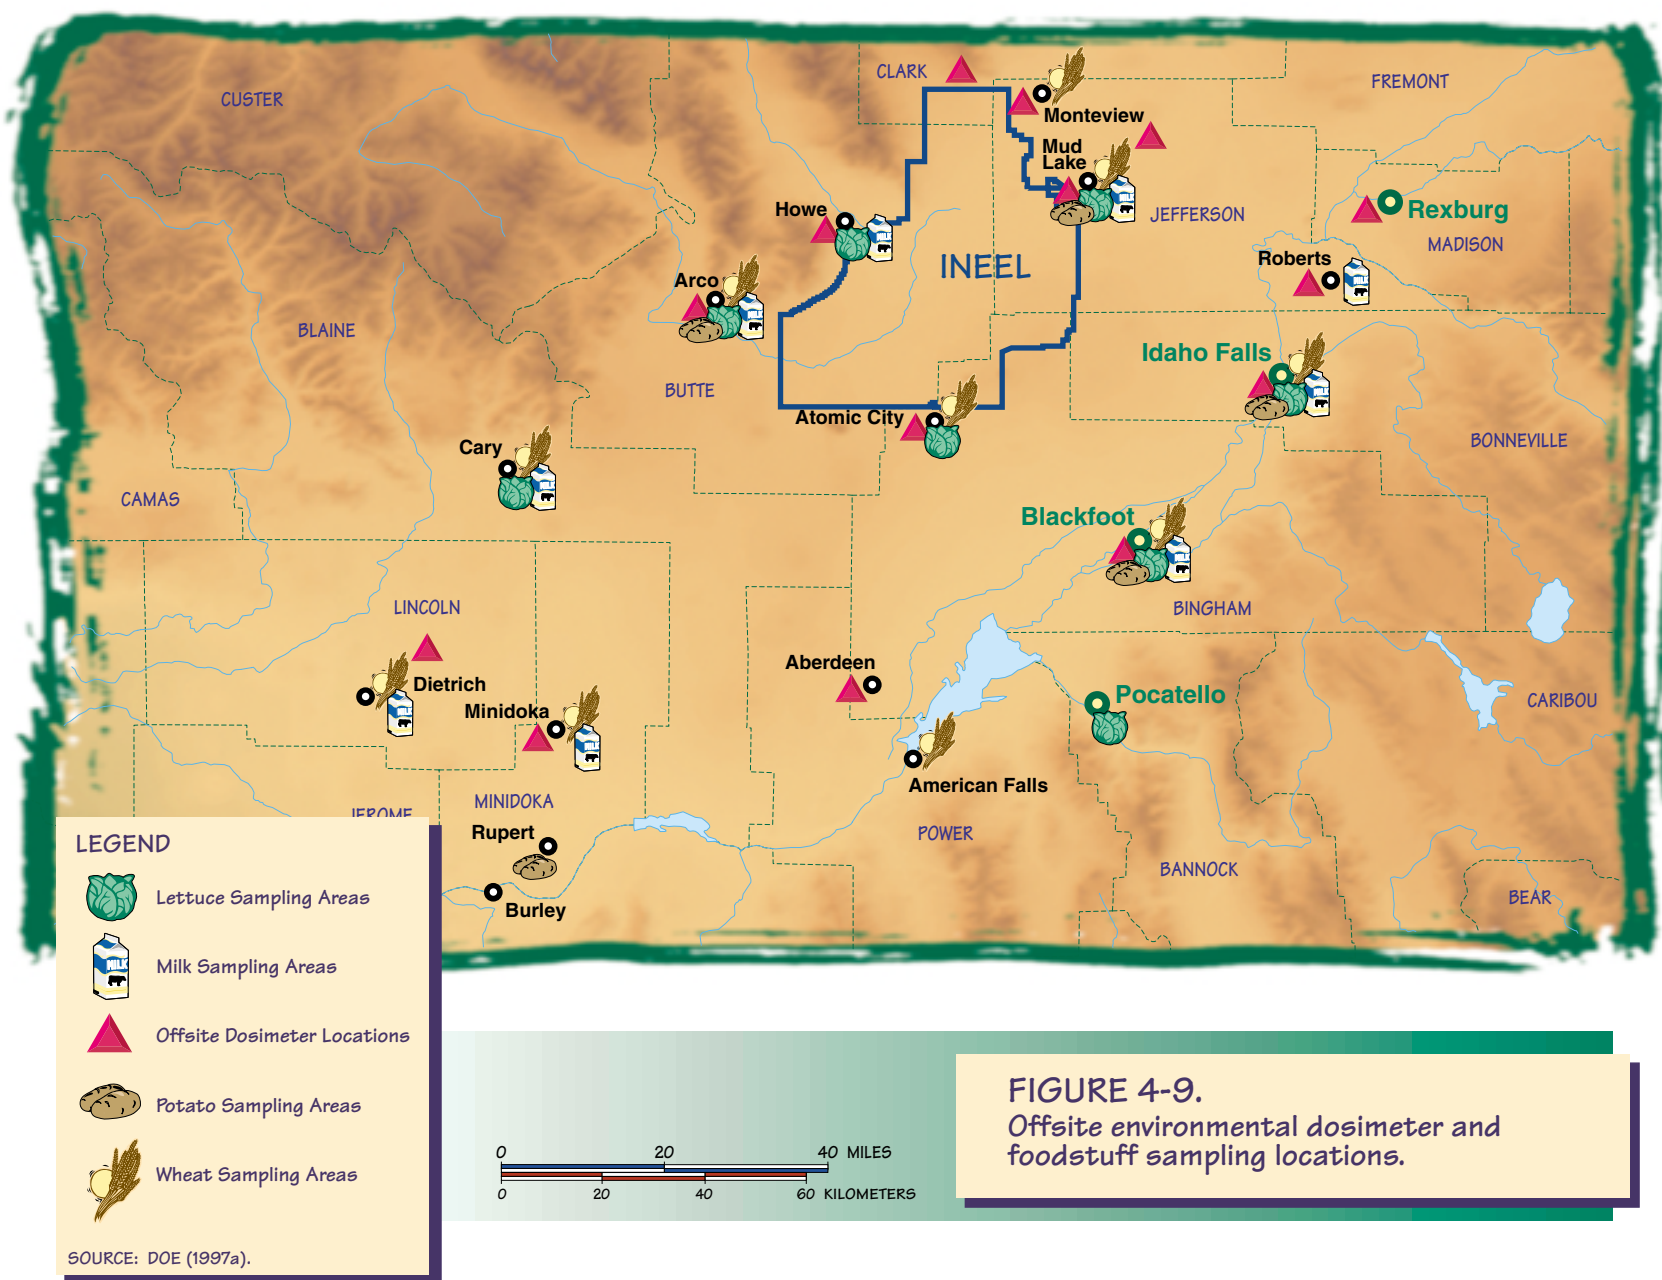

DOE compared radiation levels monitored on and near INEEL with those monitored at distant locations to determine radiological conditions. Figure 4-9 shows the offsite dosimeter locations, as well as locations where various food products are collected for radioactivity analysis. Results from onsite and boundary community locations include contributions from background conditions and INEEL emissions. Distant locations represent background conditions beyond the influence of INEEL emissions. These data show that over the most recent 5-year period for which results are available (1992 through 1996), average radiation exposure levels for the boundary locations were no different than those at distant stations. The average annual dose measured by the Environmental Science and Research Foundation, Inc. during 1996 was 123 millirem for distant locations and 124 millirem for boundary community locations. The corresponding averages measured were 127 millirem for the distant group and 125 millirem for the boundary group. These differences are well within the range of normal variation. On INEEL, dosime-

ters around some facilities may show slightly elevated levels, since many are intentionally placed to monitor dose rate in areas adjacent to radioactive material storage areas or areas of known soil contamination (DOE 1997a).

Additional environmental monitoring is also conducted by the State of Idaho's INEEL Oversight Program. The Oversight Program routinely samples the air, groundwater, soil, and milk on and around INEEL and has also established a network of stations using pressurized ion chambers for real time radiation monitoring around the site. The Oversight Program also conducts special studies in environmental monitoring as needed.

Onsite Doses

The SNF & INEL EIS (Volume 2, Section 4.7) assessed the radiation dose to workers at major INEEL facility areas that results from radionuclide emissions from INEEL facilities. For purposes of radiological assessment, such a person is referred to as a “noninvolved” worker since the worker is not directly working with the source of the exposure being assessed (such as airborne radionuclide releases from adjacent or distant facilities). The SNF & INEL EIS analysis (Section 4.7.3.2.1) indicated that a representative value for maximum dose at any onsite area resulting from existing sources and other sources expected (at the time the analysis was performed) to become operational before 1995 was 0.32 millirem per year. However, that projected dose includes contributions from activities (e.g., compacting and sizing activities at the Waste Experimental Reduction Facility) which are not expected to operate over the period covered by this EIS. An update of the maximum onsite dose is described in Appendix C.2; the revised estimate is 0.21 millirem per year. This dose is a very small fraction of the DOE-established occupational dose limit (5,000 millirem per year) and is below the National Emissions Standards for Hazardous Air Pollutants dose limit of 10 millirem per year. This limit applies to the maximally exposed member of the public (not to workers) but is the most restrictive limit for airborne releases and serves as a useful comparison.

Offsite Doses

The offsite population could receive a radiation dose as a result of radiological conditions directly attributable to INEEL operations. The dose associated with radiological emissions is assessed annually to demonstrate compliance with the National Emissions Standards for Hazardous Air Pollutants. The effective annual dose equivalent to the maximally exposed individual resulting from radionuclide emissions from INEEL facilities during 1995 and 1996 has been estimated at 0.018 millirem and 0.031 millirem, respectively (DOE 1996, 1997b). These doses are well below both the Environmental Protection Agency dose limit (10 millirem per year) and the dose received from background sources (about 360 millirem per year).

The SNF & INEL EIS provides an estimate of the collective dose to the population surrounding INEEL as a result of air emissions from all facilities that were expected (at the time the analysis was performed) to become operational before June 1, 1995. The annual collective dose to the surrounding population, based on 1990 U.S. Census Bureau data, was estimated at 0.3 person-rem. This dose applies to a total population of about 120,000 people (based on 1990 U.S. Census Bureau data), resulting in an average individual dose of less than 3×10^{-3} millirem. For comparison, this population receives an annual collective dose from background sources of about 43,000 person-rem. An update of the existing population dose is described in Appendix C.2; the revised estimate is about 0.09 person-rem per year.

It should be noted that the collective dose depends not only on the types and levels of emissions, but also on the size and distribution pattern of the surrounding population. Population data were derived from the Census Bureau Tiger/Line files. When a census tract lay partly with the 50-mile INTEC radius, it was assumed that the fraction of the population within the 50-mile radius was proportional to the area within the radius. The future baseline population dose could increase even if emission rates do not change. If emission rates remained constant, the collective dose would increase by an amount that corresponds directly to the population growth rate.

Foreseeable Increases to Baseline

DOE also considered the dose contributed by other foreseeable INEEL projects (that is, projects other than those associated with waste processing alternatives or facility disposition). Estimated annual doses from foreseeable projects are documented in Appendix C.2, (Table C.2-8). The combined effects of existing and foreseeable sources result in the following annual baseline doses:

- Noninvolved worker - 0.29 millirem
- Maximum offsite individual - 0.16 millirem
- Population - 0.92 person-rem

4.7.3.3 Summary of Radiological Conditions

Radioactivity and radiation levels resulting from INEEL air emissions are very low, well within applicable standards, and negligible when compared to doses received from natural background sources. These levels apply to onsite conditions to which INEEL workers or visitors may be exposed and offsite locations where the general population resides. Health risks associated with maximum potential exposure levels in the onsite and offsite environments are described later Section 4.11, Health and Safety.

4.7.4 NONRADIOLOGICAL CONDITIONS

Persons in the Eastern Snake River Plain are exposed to sources of air pollutants, such as agricultural and industrial activities, residential wood burning, wind-blown dust, and automobile exhaust. Many of the activities at INEEL also emit air pollutants. The types of pollutants that are assessed here include (a) the criteria pollutants regulated under the National and State Ambient Air Quality Standards and (b) other types of pollutants with potentially toxic properties called toxic (or hazardous) air pollutants. Criteria pollutants are nitrogen dioxide, sulfur dioxide, carbon monoxide, lead, ozone, and respirable particulate matter less than or equal to 10

microns in size (particles that are small enough to pass easily into the lower respiratory tract), for which National Ambient Air Quality Standards have been established. Volatile organic compounds and nitrogen oxides are assessed as precursors leading to the development of ozone. Toxic air pollutants include cancer-causing agents, such as arsenic, benzene, carbon tetrachloride, and formaldehyde, as well as substances that pose noncancer health hazards, such as fluorides, ammonia, and hydrochloric and sulfuric acids.

4.7.4.1 Sources of Air Emissions

The types of nonradiological emissions from INEEL facilities and activities are similar to those of other major industrial complexes.

Combustion sources such as thermal treatment processes, boilers, and emergency generators emit both criteria and toxic air pollutants. Sources such as nonthermal chemical processing operations, waste management activities (other than combustion), and research laboratories emit primarily toxic air pollutants. Waste management, construction, and related activities (such as excavation) also generate fugitive particulate matter.

The SNF & INEL EIS (Volume 2, Section 4.7) characterizes baseline emission rates for existing facilities for two separate cases. The actual emissions case represented the collective emission rates of nonradiological pollutants experienced by INEEL facilities during 1991 for criteria pollutants and 1989 for toxic air pollutants. The maximum emissions case represented a scenario in which all permitted sources at INEEL are assumed to operate in such a manner that they emit specific pollutants to the maximum extent allowed by operating permits or applicable regulations. These emissions were also adjusted to take projected increases (through June 1995) into account.

Actual INEEL-wide emissions for 1996 and 1997 are presented in DOE/ID-10594 and DOE/ID-10646, respectively (DOE 1997c; DOE 1998). Table 4-10 presents a comparison of actual criteria pollutant emissions during 1996 and 1997 with levels previously assessed in the SNF & INEL EIS under the maximum emissions case. For each criteria pollutant, the current (1996 to 1997) emission rates are less than the levels assessed in the SNF & INEL EIS. In the case of lead, the annual average emission rate for 1997 was about 80 percent of the level in the SNF & INEL EIS. For volatile organic compounds, the SNF & INEL EIS assessed levels of individual compounds but did not identify the combined emission rate. For all other criteria pollutants, the levels assessed in the SNF & INEL EIS are greater than actual 1996-1997 emission rates by a wide margin. Appendix C.2 (Table C.2-15) describes the ambient air concen-

trations of criteria air pollutants, including lead, which are associated with actual 1997 INEEL emissions.

It should also be noted that the New Waste Calcining Facility, which historically has been the single largest source of nitrogen dioxide emissions at the INEEL, did not operate during 1996 (DOE 1997a). In this EIS, DOE analyzes the effects of the New Waste Calcining Facility in conjunction with the specific waste processing alternatives with which this facility is associated.

DOE has also conducted a screening level risk assessment to evaluate potential adverse human health and environmental effects that could result from the continued operation of the New Waste Calcining Facility. This evaluation included the operation of the calciner, as well as related systems such as the High-Level Liquid Waste Evaporator and Liquid Effluent Treatment and Disposal Facility. The results of this evaluation demonstrate that all the potential excess cancer risk, noncarcinogenic health effects, lead exposure, and short-term air concentrations are within acceptable EPA or state limits. One compound (1,3-dinitrobenzene) evaluated in the Screening Level Ecological Risk Assessment exceeded its Ecologically-Based Screening

Level (EBSL) at its maximum point. The average soil concentration for this contaminant in the area of major depositional impact was less than the EBSL. In addition, actual impacts would be significantly less because of conservatism in emissions calculations (Abbott et al. 1999).

The SNF & INEL EIS identifies 26 toxic air pollutants that were emitted from INEEL facilities in quantities exceeding the screening level established by the State of Idaho. (The health hazard associated with toxic air pollutants emitted in lesser quantities is considered low enough by the State of Idaho not to require detailed assessment.) For a few toxic air pollutants, actual 1996 emissions were greater than the levels assessed in the SNF & INEL EIS. These increases were primarily attributable to decontamination and decommissioning activities.

The specific regulations governing toxic emissions from alternatives proposed in this EIS are contained in Sections 585 (for non-carcinogenic toxic air pollutants) and 586 (for carcinogens) of Rules for the Control of Air Pollution in Idaho. Unlike criteria pollutants, the toxic standards apply only to incremental increases of these pollutants, and not the sum of baseline levels and incremental increases.

Table 4-10. Comparison of recent criteria air pollutant emissions estimates for INEEL with the levels assessed under the maximum emissions case in the SNF & INEL EIS.

Pollutant	SNF & INEL EIS		Actual sitewide emissions					
	Maximum baseline case		1996 ^a			1997 ^b		
	Maximum hourly (kg/hr)	Annual average (kg/yr)	Actual hourly (kg/hr)	Maximum hourly (kg/hr)	Annual average (kg/yr)	Actual hourly (kg/hr)	Maximum hourly (kg/hr)	Annual average (kg/yr)

a. Source: (DOE 1997c).

b. Source: (DOE 1998).

c. The particle size of particulate matter emissions is assumed to be in the respirable range (less than 10 microns).

d. VOCs = volatile organic compounds, excluding methane.

e. ns = not specified; the SNF & INEL EIS (Section 4.7) evaluated emissions of specific types of VOCs from individual facilities, but did not include a total for the maximum baseline case.

4.7.4.2 Existing Conditions

The assessment of nonradiological air quality described in the SNF & INEL EIS was based on the assumption that the available monitoring data are not sufficient to allow a meaningful characterization of existing air quality and that such a characterization must rely on an extensive program of air dispersion modeling. The modeling program applied for this purpose utilized computer codes, methods, and assumptions that are considered acceptable by the Environmental Protection Agency and the State of Idaho for regulatory compliance purposes. The methodology applied in the assessments performed for the SNF & INEL EIS is described in Appendix F-3 of that document. The remainder of this section describes the results of the assessments in the SNF & INEL EIS for air quality conditions in the affected environment (i.e., concentrations of pollutants in air within and around INEEL). Potential changes in the affected air environment resulting from changes in INEEL emission levels (compared to those at the time the assessments in the SNF & INEL EIS were performed) are also discussed.

Onsite Conditions

The SNF & INEL EIS contains an assessment of existing conditions as a result of cumulative toxic air pollutant emissions from sources located within all areas of INEEL. Criteria pollutant levels were assessed only for ambient air locations, (i.e., locations to which the general public has access.) The onsite levels were compared to occupational exposure limits established to protect workers. With one exception, the estimated onsite concentrations were estimated at levels well below the occupational standards. The exception was for maximum short-term benzene concentration, which slightly exceeded the standard at the maximum predicted location within the Central Facilities Area. Those levels result primarily from gasoline and diesel fuel storage tank emissions at the Central Facilities Area-754 Tank Farm; however, those tanks were taken out of service in 1995, and current benzene levels are estimated to be below the occupational standard for that substance.

Offsite Conditions

Estimated maximum offsite pollutant concentrations were assessed in the SNF & INEL EIS for locations along the INEEL boundary, public roads within the site boundary, and at Craters of the Moon Wilderness Area. The results for baseline criteria pollutant levels (i.e., levels associated with facilities that existed or were projected to operate before mid-1995) are presented in the SNF & INEL EIS. These results, summarized in Table 4-11, indicate that all concentrations are well within the ambient air quality standards.

In the SNF & INEL EIS, concentrations of criteria pollutants from existing INEEL sources were also compared to Prevention of Significant Deterioration criteria (called “increments”), which have been established to ensure that air quality remains good in those areas that are in compliance with ambient air quality standards (see Appendix C.2, Section C.2.2.2 for a description of these regulations). These Prevention of Significant Deterioration increments are allowable increases over baseline conditions from sources that have become operational after certain baseline dates. Increments have been established for sulfur dioxide, respirable particulates, and nitrogen dioxide. The National Park Service establishes classifications for air quality. Separate increments are established for pristine areas, such as national parks or wilderness areas (termed Class I areas; see Section 4.5, Aesthetic and Scenic Resources, for a description of the Visual Resource Management ratings) and for the nation as a whole (Class II areas). Craters of the Moon Wilderness Area is the Class I area nearest INEEL, while the site boundary and public roads are the applicable Class II areas.

The amount of increment consumed by existing sources subject to Prevention of Significant Deterioration regulation has been updated for this EIS. Table 4-12 presents results for increment consumption at Craters of the Moon Wilderness Area Class I area, and Table 4-13 presents results for the Class II area on and around INEEL. These results represent the estimated amount of Prevention of Significant Deterioration increment consumed by the effects

Table 4-11. Ambient air concentrations of criteria pollutants from the combined effects of maximum baseline emissions and projected increases.

Pollutant	Averaging time	Maximum projected concentration ($\mu\text{g}/\text{m}^3$) ^a			Applicable standard ^b ($\mu\text{g}/\text{m}^3$)	Percent of standard		
		Site boundary	Public roads	Craters of the Moon Wilderness Area		Site boundary	Public roads	Craters of the Moon Wilderness Area
Carbon monoxide	1-hour	530	1,300	140	40,000	1	3	0.3
	8-hour	170	310	30	10,000	2	3	0.3
Nitrogen dioxide	Annual	7.3	11	0.6	100	7	11	1
Sulfur dioxide	3-hour	220	600	62	1,300	17	46	5
	24-hour	53	140	11	370	15	38	3
	Annual	2.5	6.2	0.3	80	3	8	0.4
Respirable particulates ^c	24-hour	20	35	3.2	150	13	24	2
	Annual	0.77	3.5	0.12	50	2	7	0.2
Lead	Quarterly	2.0×10^{-3}	5.0×10^{-3}	1.0×10^{-4}	1.5	0.2	0.3	0.01

a. Includes contribution from existing sources and projected increases (as described in Section 4.7.3.2).

b. All standards are primary air quality standards (designed to protect public health), except for 3-hour sulfur dioxide, which is a secondary standard (designed to protect public welfare).

c. Assumes all particulate matter emissions are of respirable size (i.e., less than 10 microns). Particulate matter concentrations do not include fugitive dust from activities such as construction. Additional standards for smaller sized particles (2.5 microns and less) have been promulgated. Current air quality levels are well within the proposed standards.

of emissions from existing INEEL sources that are subject to Prevention of Significant Deterioration regulation (based on 1996 data). The results indicate that the amount of increment consumed at the Craters of the Moon Wilderness Area Class I area by these sources does not exceed 15 percent of the allowable increment for all annual averages and 38 percent for levels assessed over shorter time periods. For the Class II area represented by public access locations on or near INEEL, the maximum consumption is 56 percent and applies to respirable particulate matter levels averaged over a worst-case 24-hour period. It should be noted that these results do not include emissions from the New Waste Calcining Facility, which is evaluated in Section 5.2.6 as part of the waste processing alternatives.

The SNF & INEL EIS assessed concentrations of toxic air pollutants and compared the results to the ambient air standards promulgated for new sources by the State of Idaho Rules for Control of Air Pollution in Idaho. These standards are increments that apply only to new or modified sources and not to existing emissions.

Nevertheless, these increments were used as “reference levels” for comparing existing and projected conditions with recommendations for ensuring public health protection in association with new sources of emissions. Annual average concentrations of carcinogenic toxics were assessed for offsite locations (site boundary and Craters of the Moon Wilderness Area), while levels of noncarcinogenic toxics were assessed for locations along public roads as well as at these offsite locations.

Highest offsite concentrations of carcinogenic toxics (summarized in Table 4.7-7 of the SNF & INEL EIS) were predicted to occur at the site boundary due south of the Central Facilities Area. All carcinogenic air pollutant levels were below the reference levels. Predicted noncarcinogenic air pollutant levels (Table 4.7-8 of the SNF & INEL EIS) were also well below the reference levels (1 percent or less) at all site boundary locations. Levels at some public road locations, which are closer to emissions sources, are higher than site boundary locations but still well below the reference levels.

Table 4-12. Prevention of Significant Deterioration increment consumption at the Craters of the Moon Class I area by sources subject to Prevention of Significant Deterioration regulation.

Pollutant	Averaging time	Allowable PSD increment ^a ($\mu\text{g}/\text{m}^3$)	Maximum predicted concentration ^b ($\mu\text{g}/\text{m}^3$)	Percent of PSD increment consumed
Sulfur dioxide	3-hour	25	6.2	25
	24-hour	5	1.9	38
	Annual	2	0.09	4.5
Respirable particulates ^c	24-hour	8	0.7	8.8
	Annual	4	8.0×10^{-3}	0.2
Nitrogen dioxide	Annual	2.5	0.06	2.3

a. All increments specified are State of Idaho standards.

b. Includes contributions from existing sources and projected increases from planned projects, including the Advanced Mixed Waste Treatment Project. For purposes of analysis, the New Waste Calcining Facility is not treated as an existing source, but rather is evaluated in Section 5.2.6 as part of the waste processing alternatives.

c. Data on particulate size are not available for most sources. For purposes of comparison to the respirable particulate increments, it is conservatively assumed that all particulates emitted are of respirable size (i.e., 10 microns or less in diameter).

PSD = Prevention of Significant Deterioration.

Table 4-13. Prevention of Significant Deterioration increment consumption at Class II areas at Idaho National Engineering and Environmental Laboratory by sources subject to Prevention of Significant Deterioration regulation.

Pollutant	Averaging time	Allowable PSD increment ^a ($\mu\text{g}/\text{m}^3$)	Maximum predicted concentration ^b		Amount of increment consumed ($\mu\text{g}/\text{m}^3$)	Percent of PSD increment consumed ^c
			INEEL boundary	Public roads		
Sulfur dioxide	3-hour	510	94	140	140	27
	24-hour	91	17	31	31	34
	Annual	20	1.9	2.4	2.4	12
Respirable particulates ^d	24-hour	30	8.4	17	17	56
	Annual	17	0.1	0.92	0.92	5.4
Nitrogen dioxide	Annual	25	1.5	1.6	1.6	6.3

a. All increments specified are State of Idaho standards.

b. Includes contributions from existing sources and projected increases from planned projects, including the Advanced Mixed Waste Treatment Project. For purposes of analysis, the New Waste Calcining Facility is not treated as an existing source, but rather is evaluated in Section 5.2.6 as part of the waste processing alternatives.

c. The amount of increment consumed is equal to the highest value of either the site boundary or public road locations; includes contributions from existing sources and projected increases from planned projects, including the Advanced Mixed Waste Treatment Project.

d. Data on particulate size are not available for most sources. For purposes of comparison to the respirable particulate increments, it is conservatively assumed that all particulates emitted are of respirable size (i.e., 10 microns or less in diameter).

PSD = Prevention of Significant Deterioration.

4.7.4.3 Summary of Nonradiological Air Quality

The air quality on and around INEEL is good and within applicable guidelines. The area around the INEEL is either in attainment or unclassified for all National Ambient Air Quality Standards. Levels of criteria pollutants assessed in the SNF & INEL EIS were found to be well within applicable standards for the maximum emissions scenario. Changes in criteria pollutant emission rates since the assessments in the SNF & INEL EIS were performed are not of

a magnitude to affect those findings. For toxic emissions, all INEEL boundary and public road levels have been found to be well below reference levels appropriate for comparison. Current emission rates for some toxic pollutants are higher than the baseline levels assessed in the SNF & INEL EIS, but resulting ambient concentrations are expected to remain below reference levels. Similarly, all toxic pollutant levels at onsite locations are expected to remain below occupational limits established for protection of workers.
